7.5 Bipartite Matching

Matching

Matching.

- Input: undirected graph G = (V, E).
- $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Max matching: find a max cardinality matching.

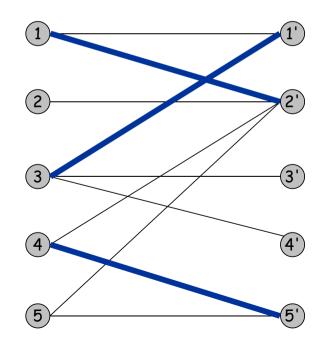

Bipartite Matching

Bipartite matching.

- Input: undirected, bipartite graph $G = (L \cup R, E)$.
- $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Max matching: find a max cardinality matching.

Def. A graph G is bipartite if the nodes can be partitioned into two subsets L and R such that every edge connects a node in L with a node in R.

matching

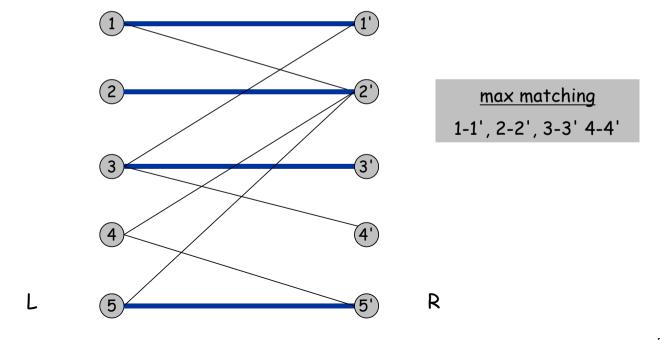

1-2', 3-1', 4-5'

R

Bipartite Matching

Bipartite matching.

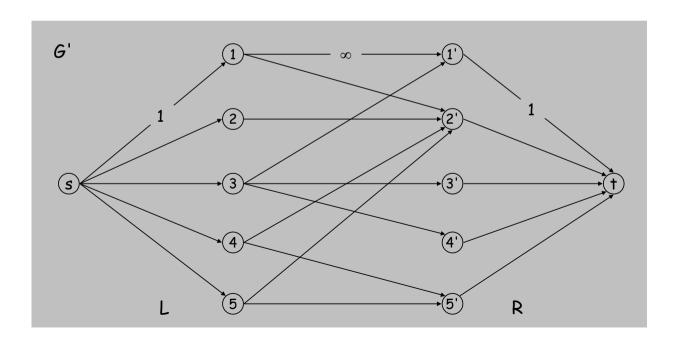

- Input: undirected, bipartite graph $G = (L \cup R, E)$.
- $M \subseteq E$ is a matching if each node appears in at most one edge in M.
- Max matching: find a max cardinality matching.

Bipartite Matching

Max flow formulation.

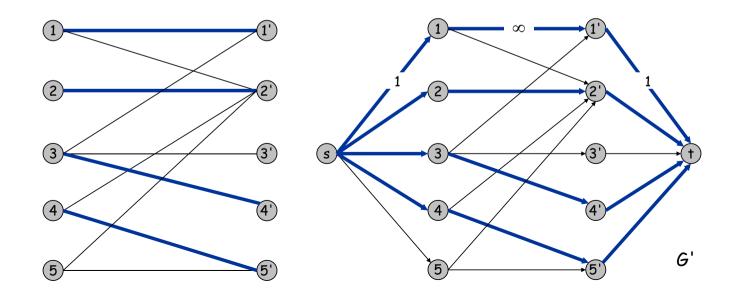

- Create digraph $G' = (L \cup R \cup \{s, t\}, E')$.
 - Direct all edges from L to R, and assign infinite (or unit) capacity.
 - Add source s, and unit capacity edges from s to each node in L.
 - Add sink t, and unit capacity edges from each node in R to t.

Bipartite Matching: Proof of Correctness

Theorem. value of max flow in G' = Max cardinality matching in G. Pf. \leq

- Given max matching M of cardinality k.
- Consider flow f that sends 1 unit along each of k paths.
- f is a flow, and has cardinality k.

G

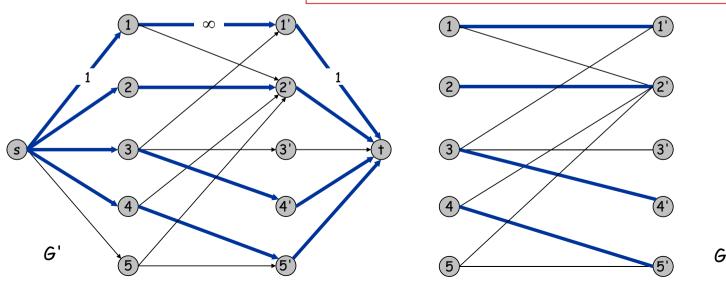

Bipartite Matching: Proof of Correctness

Theorem. value of max flow in G' = Max cardinality matching in G.

Pf. ≥

- Let f be a max flow in G' of value k.
- Integrality theorem \Rightarrow k is integral and can assume f is 0-1.
- Consider M = set of edges from L to R with f(e) = 1.
 - each node in L and R participates in at most one edge in M
 - |M| = k: apply flow-value lemma to cut $(L \cup s, R \cup t)$

Flow value lemma. Let f be any flow, and let (A, B) be any s-t cut. Then, the net flow sent across the cut is equal to the amount leaving s.

Perfect Matching

Def. A matching $M \subseteq E$ is perfect if each node appears in exactly one edge in M.

Q. When does a bipartite graph have a perfect matching?

Structure of bipartite graphs with perfect matchings.

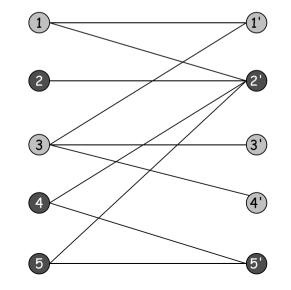

- Clearly we must have |L| = |R|.
- What other conditions are necessary?
- What conditions are sufficient?

Perfect Matching

Notation. Let S be a subset of nodes, and let N(S) be the set of nodes adjacent to nodes in S.

Observation. If a bipartite graph $G = (L \cup R, E)$, has a perfect matching, then $|N(S)| \ge |S|$ for all subsets $S \subseteq L$.

Pf. Each node in S has to be matched to a different node in N(S).

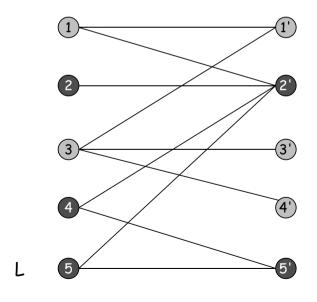

No perfect matching:

$$N(5) = \{ 2', 5' \}.$$

Hall's marriage theorem

Theorem. [Frobenius 1917, Hall 1935] Let $G = (L \cup R, E)$ be a bipartite graph with |L| = |R|. Then, graph G has a perfect matching iff $|N(S)| \ge |S|$ for all subsets $S \subseteq L$.

Pf. \Rightarrow This was the previous observation.

No perfect matching:

$$N(5) = \{ 2', 5' \}.$$

R

Bipartite Matching: Running Time

Which max flow algorithm to use for bipartite matching?

- Generic augmenting path: $O(mn \text{ val}(f^*)) = O(mnC)$.
- Capacity scaling: O(m² log C).

Non-bipartite matching.

- Structure of non-bipartite graphs is more complicated, but well-understood. [Tutte-Berge, Edmonds-Galai]
- Blossom algorithm: O(n⁴). [Edmonds 1965]
- Best known: O(m n^{1/2}). [Micali-Vazirani 1980]
